# Need for Calibration

- Currently four satellites in constellation
- Three more in 2009
- Need good absolute calibration
- More important the relative calibration for high temporal applications

# Problems of Vicarious Calibration

- Logistics and costs
  - Many satellites each requiring several acquisitions
    - Organisational issues (timing, availability)
    - Costs (ground teams and processing)
  - Growing number of satellites each year
- Technically
  - Variable number of acquisitions gives variable quality
  - Larger than desired relative (satellite to satellite) calibration variability
    - Affects customer applications (precision farming using the whole constellation)

## Calibration Activities

- In 2008-2009 changed over from individual satellite vicarious calibration to “Gold Standard” and cross-calibration
- Overview of procedure and results, plus uncertainties (where possible) are given

# Approach Outline

- Three elements
  - Absolute calibration
    - Uses a single satellite “Gold” standard
    - More acquisitions (more confidence)
    - Lower costs as single satellite
  - Transfer calibration
    - Uses Dome-C in Antarctica to transfer from a few detectors to whole array
  - Cross-calibration
    - Intersections over Dome-C (half an image overlap – 320km) time separation of 30 minutes to one hour with stable atmosphere

## Step 1 – Absolute (Ground)

Absolute RRV						Uncertainty
	May 28 2008	June 2 2008	June 5 2008	June 18 2008	August 20 2008	2.7%

- Uncertainty based on traceability to standards
- Absolute accuracy
- Generates five TOA radiance values

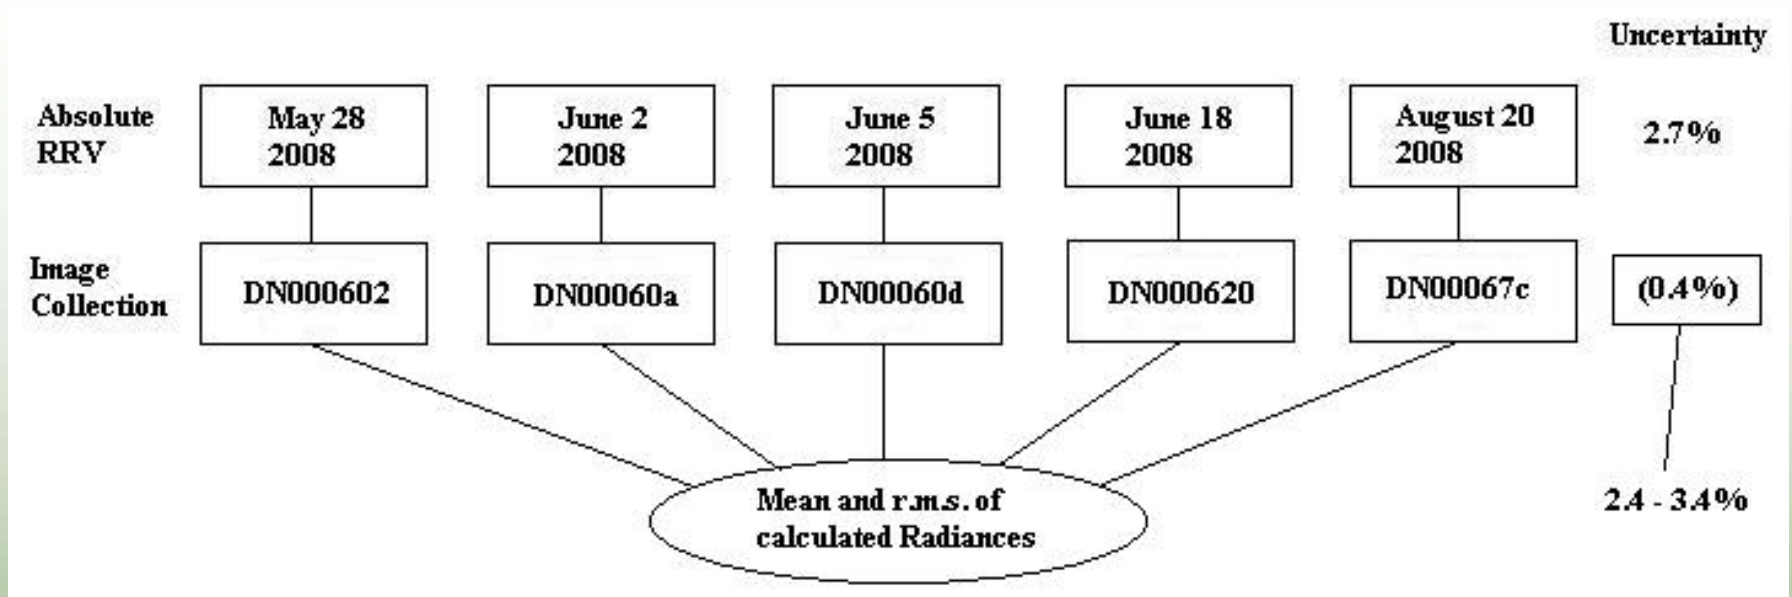

## Step 2 – Absolute (Space)

					Uncertainty	
Absolute RRV	May 28 2008	June 2 2008	June 5 2008	June 18 2008	August 20 2008	2.7%
Image Collection	DN000602	DN00060a	DN00060d	DN000620	DN00067c	(0.4%)

- Surface Variability RRV and system noise in imagery over test site at RRV
- Nine pixels for each image show a variability of 0.4% r.m.s. (NIR band)

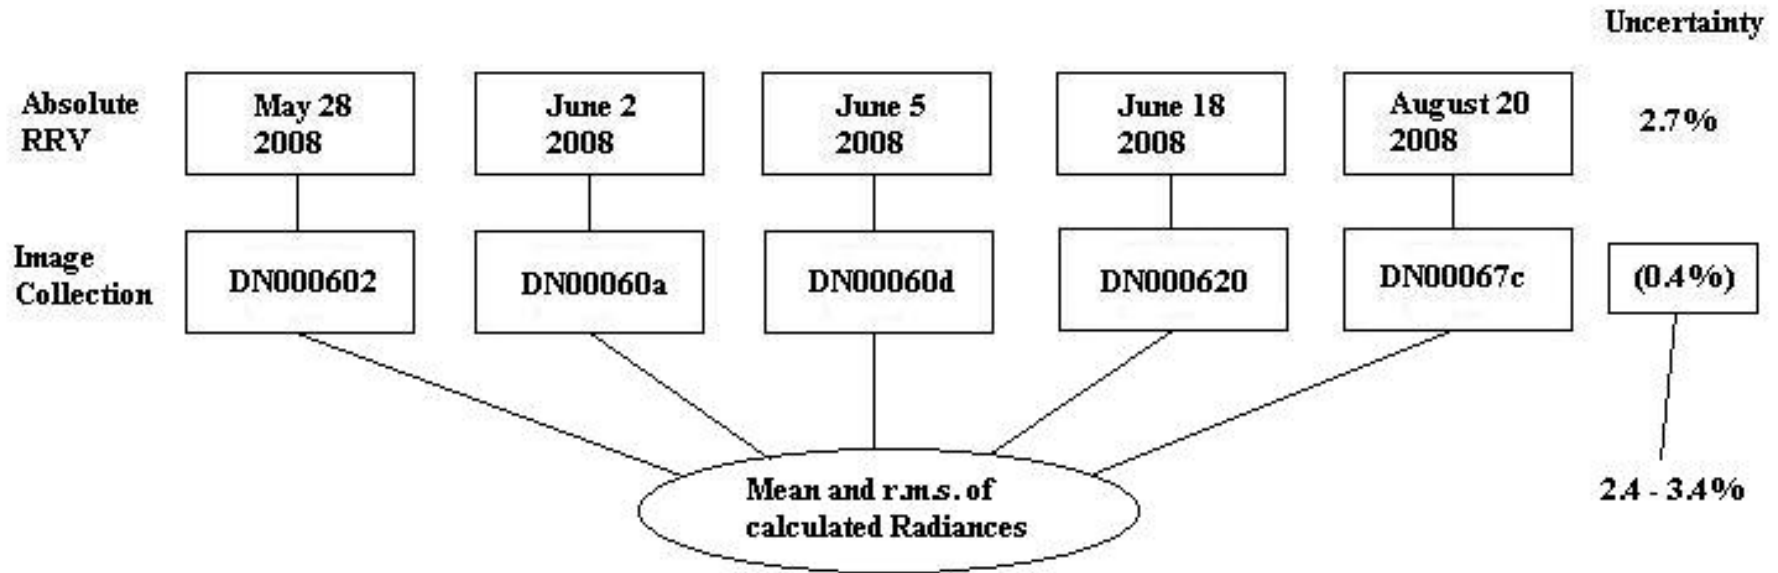

## Step 3 – Transfer Calibration

- Each image generates calibration coefficients.
- Apply to same DOME-C white image gives five different radiances.
- Variability is the uncertainty due to the repeatability of the RRV Absolute, plus sensor noise and surface variation of DOME-C and RRV.

## Step 4 – Final Calibration

- Combine the absolute accuracy term (2.7%) with the variability term (2.4% to 3.4%) to give the final absolute values
- **Green : 3.6%, Red : 3.9%, NIR : 4.3%**

# Cross-Calibration

- Uses Dome-C site. Images have between one half and full overlap.
- Time separation of 30 minutes to one hour, yawed across principal plane.
- Preparation Steps include
  - Identification of image pairs (UK-DMC-1 and Nigeriasat-1 had 19 image pairs)
  - Cloud screening to select best for final cross calibration
  - Correction for solar zenith differences
  - Variability determination by ratioing values using new Nigeriasat-1 calibration and old UK-DMC-1 calibration.

# Cross-Calibration – Step 1

Dome-C : 19 Image pairs 2008-2009

Uncertainty

Adjust Radiance Values for Solar Zenith Angle differences

0.1%

- 19 image pairs (Nigeriasat-1 against UK-DMC-1)
- Large proportion are cloudy
- Radiances of Nigeriasat-1 calculated with new coefficients
- Radiances of UK-DMC-1 calculated with old coefficients.
- Small uncertainty due to pointing accuracy (0.1%)
- Correction for solar zenith angle differences between image pairs

# Cross-Calibration – Step 2

Dome-C : 19 Image pairs 2008-2009

Uncertainty

Adjust Radiance Values for Solar Zenith Angle differences

0.1 %

Ratio Nigeriasat-1 / UK-DMC-1 radiances to get average correction factor

- Ratio varies
- Applicable to both cloudy and clear images
- Half image overlap used to generate statistics

## Cross-Calibration – Step 2

- No relationship between variation in cloud cover and change in ratio value.
- Clear image pairs were found across all ratio values

# Cross-Calibration – Step 3

Dome-C : 19 Image pairs 2008-2009

Uncertainty

Adjust Radiance Values for Solar Zenith Angle differences

0.1 %

Ratio Nigeriasat-1 / UK-DMC-1 radiances to get average correction factor

Selection of Best Image Pair and correction to mean of Ratio Values

- Selected image pair had no cloud
- Dome-C visible in both images
- Corrected radiance to be in centre of ratio distribution

# Cross-Calibration 4

Dome-C : 19 Image pairs 2008-2009

Uncertainty

Adjust Radiance Values for Solar Zenith Angle differences

0.1 %

Ratio Nigeriasat-1 / UK-DMC-1 radiances to get average correction factor

Selection of Best Image Pair and correction to mean of Ratio Values

Derived new UK-DMC-1 coefficients and cross-compared with Nigeriasat-1 data after new coefficients applied

0.46 to 0.65 %

- The uncertainties of this process can then be combined with the absolute from Nigeriasat-1 to give the following for UK-DMC-1
  - Green : 3.7%, Red : 4%, NIR : 4.4%

## Cross-Calibration 5

- Repeated for Beijing-1
- Validation between Beijing-1 and UK-DMC-1 intersections with r.m.s. of these less than 0.2%
- Absolute less than 5% for all satellites in constellation
- Relative satellite to satellite less than 1% (1 sigma)

## Modular QA/QC

- Still under development
- Some examples to be shown later this week
- Initial results are unearthing many areas of uncertainty previously ignored (electronics stability)
- Some of areas shown in this calibration exercise

An aerial photograph of a coastal region, likely a large island or a section of a coastline. The land is characterized by a dense pattern of red and white patches, which could represent different types of vegetation, snow, or a specific land use classification. The surrounding water is a dark, deep blue. The overall image has a slightly grainy, high-contrast appearance.
